Capstone Project Check Point: Strange Attractors

For the past couple of weeks since the project was assigned, we have learned LaTeX, finished the code for simulating the attractors, and are currently preparing to write the report on Overleaf. The code runs the equations for the strange attractors and visualizes it onto a 3D graph that can be rotated to see the different features of the attractor, which was done using matplotlib and PyQt5 for a GUI. In the code, we modeled the Lorenz, Thomas, Langford, and Rössler Attractors. The simulation also allows us to compare slightly different initial conditions of an attractor and make a logarithmic graph of the distances between each of their points with respect to time. We also worked on the presentation and created slides on PowerPoint with the main ideas we have learned through our readings.
